Received May 17, 1993
This article reports the first example of the oxidative addition of dioxygen to a transition-metal cluster to give a bis $\left(\mu_{3}\right.$-oxo $)$ cluster. Remarkably, this reaction leads to 4 -electron oxidation of the cluster and an increase in the cluster electron count of 8 -electrons, and it provides a simple model for the dissociative chemisorption of oxygen at a metal surface. This work adds significantly to the known value of organometallic oxo clusters as structural models for inorganic oxides and surface-bound oxide and to recent research on the dissociative addition of oxygen to multiply bonded dirhenium complexes. ${ }^{1,2}$

The coordinatively unsaturated cluster cation $\left[\mathrm{Pt}_{3}\left(\mu_{3}-\mathrm{CO}\right)(\mu-\right.$ $\left.\mathrm{dppm})_{3}\right]^{2+}(1), \mathrm{dppm}=\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{PPh}_{2}$, has been shown to be a good model for chemisorption of several small molecules at a $\mathrm{Pt}(111)$ surface, ${ }^{3}$ but it fails to react with $\mathrm{O}_{2}$. Since bimetallic $\mathrm{Pt}-\mathrm{Re}$ catalysts may be more useful than platinum alone, it was of interest to prepare coordinatively unsaturated platinumrhenium clusters as models for reactivity at the $\mathrm{Pt} / \mathrm{Re}$ surface. Reaction of 1 with $\left[\operatorname{Re}(\mathrm{CO})_{5}\right]$ - gave the new cluster cation $\left[\mathrm{Pt}_{3}-\right.$ $\left.\left\{\operatorname{Re}(\mathrm{CO})_{3}\right\}(\mu-\mathrm{dppm})_{3}\right]^{+}(2) .^{4}$ The cluster 2 was obtained as redblack crystals with either $\mathrm{PF}_{6}{ }^{-}$or $\mathrm{BPh}_{4}{ }^{-}$anions, and the structure of 2 as the $\left[\mathrm{BPh}_{4}\right]$ salt is shown in Figure $1 .{ }^{4}$ The cluster core has tetrahedral geometry, and the metal-metal bonds are short and presumably strong (Table I).

The cluster cation 2 has a valence electron count of only 54 and so is coordinatively unsaturated. ${ }^{5}$ The simplest interpretation of the bonding in 2 is that the three filled $\mathrm{M}-\mathrm{M}$ bonding orbitals ( $\mathrm{a}_{1}+\mathrm{e}$ symmetry) of a $\mathrm{Pt}_{3}(\mu \text {-dppm) })_{3}$ fragment act as donors to the three vacant acceptor orbitals (also $a_{1}+e$ symmetry) of a

[^0]

Figure 1. View of the structure of the cluster cation 2. Only the ipso carbon atoms of the dppm phenyl groups are shown. The ranges of $\mathrm{Pt}-\mathrm{P}$ and Re-C distances are 2.279(3)-2.293(3) and $1.85(1)-1.88(1) \AA$, respectively.

Table I. Comparison of Metal-Metal Distances ( $\AA$ ) in 2 and $3^{a}$

|  | 2 | 3 |
| :---: | :---: | :---: |
| $\mathrm{Pt}(1)-\mathrm{Pt}(2)$ | $2.611(1)$ | $2.826(1)$ |
| $\mathrm{Pt}(1)-\mathrm{Pt}(3)$ | $2.593(1)$ | $3.094(1)$ |
| $\mathrm{Pt}(2)-\mathrm{Pt}(3)$ | $2.608(1)$ | $3.081(1)$ |
| $\mathrm{Pt}(1)-\operatorname{Re}$ | $2.684(1)$ | $2.843(1)$ |
| $\mathrm{Pt}(2)-\operatorname{Re}$ | $2.649(1)$ | $2.854(1)$ |
| $\mathrm{Pt}(3)-\operatorname{Re}$ | $2.685(1)$ | $3.228(1)$ |

${ }^{a}$ The accepted range for $\mathrm{Pt}-\mathrm{Pt}$ bonded distances is $2.6-2.8 \AA$, and values for 1 are 2.613(1)-2.650(1) $\AA$. Previous values for $d(\mathrm{Pt}-\mathrm{Re})$ fall in the range $2.71-2.91 \AA$, with almost half in the range $2.83-2.87 \AA$. The Pt-Re distances in 2 appear to be the shortest known. ${ }^{9}$
$\operatorname{Re}(\mathrm{CO})_{3}{ }^{+}$fragment. ${ }^{6.7}$ In this way, each Pt atom shares 16 and the Re atom shares 18 valence electrons. However, several small molecules such as CO and $\mathrm{HC} \equiv \mathrm{CH}$ add rapidiy to 2 at the rhenium center to give $\left[\mathrm{Pt}_{3}\left\{\operatorname{Re}(\mathrm{CO})_{3} \mathrm{~L}\right\}(\mu \text {-dppm })_{3}\right]^{+}$, indicating that rhenium is the major site of unsaturation.

Of particular interest is the reaction of $\mathrm{O}_{2}$ with solutions of 2 to give the orange dioxo cluster $\left[\mathrm{Pt}_{3}\left\{\operatorname{Re}(\mathrm{CO})_{3}\right\}\left(\mu_{3}-\mathrm{O}\right)_{2}(\mu-\mathrm{dppm})_{3}\right]^{+}$ (3). ${ }^{8}$ This reaction takes several days to reach completion for solutions standing under 1 atm of air at room temperature, and no intermediates can be detected by NMR; the reaction is faster under pure $\mathrm{O}_{2}$, while 2 is stable under a $\mathrm{N}_{2}$ atmosphere. Remarkably, the same product 3 is formed by reaction of $\mathrm{O}_{2}$ with $\mathbf{2}$ in the solid state. The structure of the cation $\mathbf{3}$ was established by an X-ray structural analysis of the $\mathrm{PF}_{6}{ }^{-}$salt and is illustrated in Figure $2 .{ }^{8}$

The inner core of $\mathbf{3}$ contains a slightly distorted tetrahedron of metal atoms in which two $\mathrm{Pt}_{2} \mathrm{Re}$ faces are now capped by $\mu_{3}$-oxo bridging atoms in a nearly symmetric fashion. The incorporation of two $\mu_{3}-\mathrm{O}$ capping units is accompanied by a

[^1]

Figure 2. View of the cluster cation 3, showing $50 \%$ probability ellipsoids. Only the ipso carbon atoms of the dppm phenyl groups are shown. The ranges of Pt-P and Re-C distances are 2.227(3)-2.243(3) and 1.89-(1)-1.89(1) $\AA$, respectively. Metal-oxygen distances are $\mathrm{Pt}(1)-\mathrm{O}(\mathrm{Br} 2)$ 2.049(6), $\mathrm{Pt}(2)-\mathrm{O}(\mathrm{Br} 1) 2.065(6), \mathrm{Pt}(3)-\mathrm{O}(\mathrm{Br} 1) 2.036(6), \mathrm{Pt}(3)-\mathrm{O}(\mathrm{Br} 2)$ 2.046(6), $\mathrm{Re}-\mathrm{O}(\mathrm{Br} 1)$ 2.117(6), and $\operatorname{Re}-\mathrm{O}(\mathrm{Br} 2) 2.121(6) \mathrm{A}$.
significant lengthening of all the metal-metal distances compared to those in 2 (Table I). The distances within the $\mathrm{Pt}(1) \mathrm{Pt}(2) \mathrm{Re}$ triangle are still clearly in the bonding region, but the $\mathrm{Pt}(1) \ldots \mathrm{Pt}-$ (3), $\mathrm{Pt}(2) \cdots \mathrm{Pt}(3)$, and $\mathrm{Pt}(3) \cdots \operatorname{Re}$ distances are borderline or nonbonding. ${ }^{9}$ In contrast, a $\mu_{3}$-oxo ligand causes shortening of metal-metal bonds in some other clusters, where the electron count does not change. ${ }^{2}$ Since a $\mu_{3}$-O ligand donates 4 electrons, the electron count in 3 is 62 , compared to only 54 in 2 , and so cleavage of $\mathrm{M}-\mathrm{M}$ bonds is expected. ${ }^{5}$ The bonding in $\mathbf{3}$ may be described in terms of two 16 -electron $\mathrm{Pt}(\mathrm{I})$ atoms, $\mathrm{Pt}(1)$ and $\mathrm{Pt}(2)$, having similar distorted square-planar $\mathrm{PtOP}_{2}$ centers with a $\mathrm{Pt}(1)-\mathrm{Pt}(2)$ bond, a square-planar 16 -electron $\mathrm{Pt}(\mathrm{II})$ atom, $\mathrm{Pt}(3)$, with a cis $-\mathrm{PtO}_{2} \mathrm{P}_{2}$ center, and an octahedral fac-Re(I)$(\mathrm{O})_{2}(\mathrm{CO})_{3}$ center which completes an 18 -electron configuration by accepting two electrons from the $\mathrm{Pt}(1)-\mathrm{Pt}(2)$ bond. The valence bond representations of 2 and 3 are then clearly related (Scheme I) and may be used to rationalize the remarkable increase in electron count without any ligand dissociation. A similar

[^2]Scheme I (Top) Formation of 3; (bottom), Simplified VB Representations

bonding scheme has been proposed for the dioxo-capped cluster $\left.\left\{\mathrm{Pt}_{4} \mathrm{Cl}_{2}\left(\mu_{3}-\mathrm{O}\right)_{2} \text { (dmso) }\right)_{6}\right]$ (dmso $=$ dimethyl sulfoxide). ${ }^{10}$

Cluster $\mathbf{3}$ was also formed when $\mathbf{2}$ was treated with the oxygen atom donor $\mathrm{Me}_{3} \mathrm{NO}$ in the absence of $\mathrm{O}_{2}$. Interestingly, an intermediate cluster 4 was detected by NMR in this reaction and is tentatively suggested to be the mono-oxo adduct. ${ }^{11}$ No such intermediate was detected in the reaction of 2 with $\mathrm{O}_{2}$, and, together with 'he observation that the reaction also occurs with 2 in the solid state, this strongly suggests that the formation of 3 from 2 and $\mathrm{O}_{2}$ occurs by a concerted mechanism. It is likely that $\mathrm{O}_{2}$ first adds to the rhenium center, and then $\mathrm{O}-\mathrm{O}$ bond cleavage occurs as the oxygen atoms migrate to the $\mathrm{Pt}_{2} \mathrm{Re}$ faces. There is a remarkable resemblance to chemisorption, which leads to $\mathrm{M}_{3}\left(\mu_{3}-\mathrm{O}\right)$ units on either platinum or rhenium surfaces and, at least for platinum, is thought to occur via an intermediate $\mathrm{O}_{2}$ complex. ${ }^{18, h}$ Of course, the ability of metal surfaces to bind oxygen is important in catalytic oxidation reactions, and so it is also significant that 2 is a catalyst for the oxidation of $\mathrm{Ph}_{3} \mathrm{P}^{\text {to }} \mathrm{Ph}_{3} \mathrm{P}=\mathrm{O}$ by $\mathrm{O}_{2}$ (turnover number at room temperature $=1 \mathrm{~mol}(\mathrm{~mol} 2)^{-1}$ $\left.\mathrm{h}^{-1}\right)$. Clearly the type of $\mathrm{Pt}_{2} \operatorname{Re}\left(\mu_{3}-\mathrm{O}\right)$ units established in this work could also be present in oxide supported bimetallic Pt-Re catalysts.
